Sprint 2:

I implemented US-05 (Job search and filtering). On the frontend, I defined the job interface and first built styled job listing cards from sample data (Task 5.3). I then added a work mode field (on-site, remote, hybrid) to the job posts on the backend and matched the frontend type to the schema. I built the job search API endpoint (`GET /api/jobs`), which returns only open jobs, newest first, to logged-in users, with keyword search on the title, company and description, and filters for location, category, job type, and work mode (Task 5.1), and added database indexes for the search fields (Task 5.2). I connected the job dashboard to the search API, with filters that update as the user types, a clear button, loading and empty states, and an expandable detail view showing the full job description and salary (Tasks 5.3, 5.4), and created 13 backend tests for the search endpoint, which run in our CI pipeline. The work was merged through PR #96.

I generated acceptance tests using a template for the user stories for Sprints 1 and 2 (14 in total, two per user story), with a clear `acceptance test` tag and linked to their respective user stories as sub-issues. I then updated the work plan with new tasks and the acceptance tests. I also documented my AI usage in my Sprint 2 AI log.
